Bird recognition in the city of Peacetopia (case study)
Quiz, 15 questions
15/15 points (100%) \leftarrow 1.

Problem Statement

This example is adapted from a real production application, but with details disguised to protect confidentiality.

You are a famous researcher in the City of Peacetopia. The people of Peacetopia have a common characteristic: they are afraid of birds. To save them, you have **to build an algorithm that will detect any bird flying over Peacetopia** and alert the population.

The City Council gives you a dataset of 10,000,000 images of the sky above Peacetopia, taken from the city's security cameras. They are labelled:

- y = 0: There is no bird on the image
- y = 1: There is a bird on the image

Your goal is to build an algorithm able to classify new images taken by security cameras from Peacetopia.

There are a lot of decisions to make:

- What is the evaluation metric?
- How do you structure your data into train/dev/test sets?

Metric of success

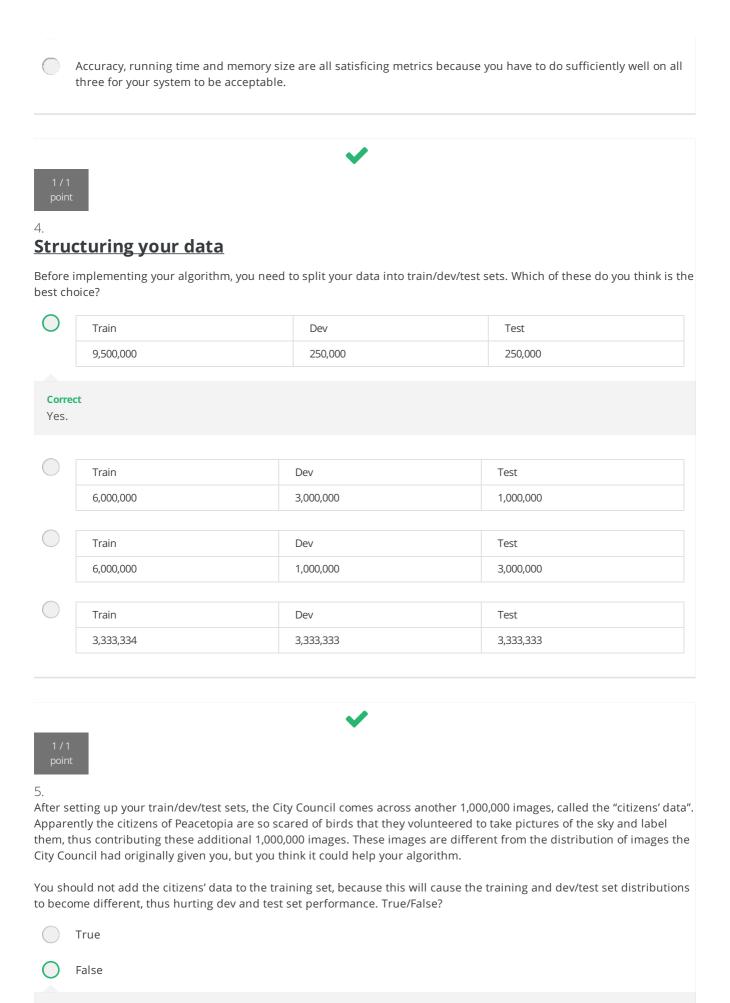

The City Council tells you that they want an algorithm that

- 1. Has high accuracy
- 2. Runs quickly and takes only a short time to classify a new image.
- 3. Can fit in a small amount of memory, so that it can run in a small processor that the city will attach to many different security cameras.

<u>Note</u>: Having three evaluation metrics makes it harder for you to quickly choose between two different algorithms, and will slow down the speed with which your team can iterate. True/False?

on the city's requests, wl	hich of the following would you say is true	
on the city's requests, wl	hich of the following would you say is true	
on the city's requests, wl Accuracy is an optimizi		are a satisficing metrics.

Correct

Adding this data to the training set will change the training set distribution. However, it is not a problem to have different training and dev distribution. On the contrary, it would be very problematic to have different dev and test set distributions.

	A learning algorithm's performance can be better than human-level performance and	better than Bayes error.	

1/1 point

10.

You find that a team of ornithologists debating and discussing an image gets an even better 0.1% performance, so you define that as "human-level performance." After working further on your algorithm, you end up with the following:

Human-level performance	0.1%
Training set error	2.0%
Dev set error	2.1%

Based on the evidence you have, which two of the following four options seem the most promising to try? (Check two options.)

Try decreasing regularization.

Correct

Train a bigger model to try to do better on the training set.

Correct

Try increasing regularization.

Un-selected is correct

Get a bigger training set to reduce variance.

Un-selected is correct

1/1 point

11.

You also evaluate your model on the test set, and find the following:

Human-level performance	0.1%
Training set error	2.0%
Dev set error	2.1%
Test set error	7.0%

What does this mean? (Check the two best options.)

You should try to get a bigger dev set.

Correct

You have underfit to the dev set.						
Un-selected is correct						
You have overfit to the dev set.						
Correct						
You should get a bigger test set.						
Un-selected is correct						
1/1 point						
12. After working on this project for a year, you	finally achieve					
Human-level performance	0.10%					
Training set error Dev set error	0.05%					
What can you conclude? (Check all that app						
This is a statistical anomaly (or mus human-level performance.	This is a statistical anomaly (or must be the result of statistical noise) since it should not be possible to surpass human-level performance.					
Un-selected is correct						
If the test set is big enough for the 0.05% error estimate to be accurate, this implies Bayes error is ≤ 0.05						
Correct						
With only 0.09% further progress to make, you should quickly be able to close the remaining gap to 0%						
Un-selected is correct						
It is now harder to measure avoidable bias, thus progress will be slower going forward.						
Correct						

point

13.

It turns out Peacetopia has hired one of your competitors to build a system as well. Your system and your competitor both deliver systems with about the same running time and memory size. However, your system has higher accuracy! However, when Peacetopia tries out your and your competitor's systems, they conclude they actually like your competitor's system better, because even though you have higher overall accuracy, you have more false negatives (failing to raise an alarm when a bird is in the air). What should you do?

- Look at all the models you've developed during the development process and find the one with the lowest false negative error rate.
- Ask your team to take into account both accuracy and false negative rate during development.
- Rethink the appropriate metric for this task, and ask your team to tune to the new metric.

Correct

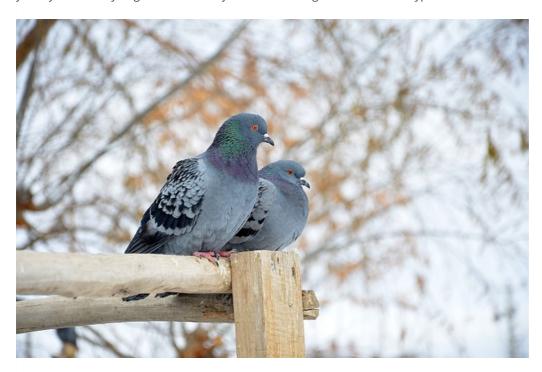

Pick false negative rate as the new metric, and use this new metric to drive all further development.

point

14.

You've handily beaten your competitor, and your system is now deployed in Peacetopia and is protecting the citizens from birds! But over the last few months, a new species of bird has been slowly migrating into the area, so the performance of your system slowly degrades because your data is being tested on a new type of data.

You have only 1,000 images of the new species of bird. The city expects a better system from you within the next 3 months. Which of these should you do first?

0

Use the data you have to define a new evaluation metric (using a new dev/test set) taking into account the new species, and use that to drive further progress for your team.

Correct

	Put the 1,000 images into the training set so as to try to do better on these birds.
	Try data augmentation/data synthesis to get more images of the new type of bird.
	Add the 1,000 images into your dataset and reshuffle into a new train/dev/test split.

the Bir Becaus	ty Council thinks that having more Cats in the city would help scare off birds. They are so happy with your work on d detector that they also hire you to build a Cat detector. (Wow Cat detectors are just incredibly useful aren't they.) see of years of working on Cat detectors, you have such a huge dataset of 100,000,000 cat images that training on this akes about two weeks. Which of the statements do you agree with? (Check all that agree.)
	If 100,000,000 examples is enough to build a good enough Cat detector, you might be better of training with just 10,000,000 examples to gain a \approx 10x improvement in how quickly you can run experiments, even if each model performs a bit worse because it's trained on less data.
Corre	ect Control of the Co
	Needing two weeks to train will limit the speed at which you can iterate.
Corre	ect
	Buying faster computers could speed up your teams' iteration speed and thus your team's productivity.
Corre	ect
	Having built a good Bird detector, you should be able to take the same model and hyperparameters and just apply it to the Cat dataset, so there is no need to iterate.
Un-s	elected is correct
